S Supporting Information

ABSTRACT: The *endo* and *exo* stereoselectivities of Diels–Alder reactions of cyclopropenone, iminocyclopropene, and substituted triafulvenes with butadiene were rationalized using density functional theory calculations. When cyclopropenone is the dienophile, there is a 1.8 kcal/mol preference for the *exo* cycloaddition with butadiene, while the reaction of 3-difluoromethylene triafulvene with butadiene favors the *endo* cycloaddition by 2.8 kcal/mol. The influence of charge transfer and secondary orbital interactions on the stereoselectivity of Diels–Alder reactions involving triafulvenes and heteroanalogues is discussed. The predicted stereoselectivity correlates with both the charge and highest occupied molecular orbital (HOMO) coefficient at the C₃ carbon of the triafulvene motif.

1. INTRODUCTION

In 1969, Breslow reported that the Diels–Alder reaction of cyclopropenone with 1,3-diphenylisobenzofuran proceeds with unusual *exo* stereoselectivity (Scheme 1).¹ Berson reinvestigated

Scheme 1. Diels–Alder Reaction of Cyclopropenone and 1,3-Diphenylisobenzofuran

this reaction in 1994 and confirmed the *exo*-selectivity of cyclopropenone with 1,3-diphenylisobenzofuran by obtaining the crystal structures of the *endo* and *exo* Diels–Alder adducts.² Analysis of the reaction kinetics at –30 °C revealed an estimated preference of 50:1 *exo/endo*.

Bachrach computationally analyzed the Diels–Alder reaction between cyclopropenone and furan at the MP2 level.³ He computed a 1.8 kcal/mol kinetic and a 6.4 kcal/mol thermodynamic preference for the *exo* adduct. The *exo* preference was attributed to a stabilizing electrostatic interaction between the oxygen atom of furan and the carbonyl carbon of the cyclopropenone in the *exo* transition state (Scheme 2).³ Recently, we computed that cyclopropenone also reacts with *exo* stereoselectivity when cyclopentadiene is the diene,⁴ in contrast to the highly *endo* selective cyclopropene.⁵ This discovery, and the fact that cyclopropenones have emerged as

Scheme 2. Stabilizing Electrostatic Interaction Proposed by Bachrach in the *Exo* Transition State for the Diels–Alder Reaction of Furan with Cyclopropenone³

stable, minimally invasive probes for bioorthogonal labeling studies,⁶ prompted us to systematically study the origins of the *endo* and *exo* Diels–Alder stereoselectivity of cyclopropenone (1), cyclopropenethione (2), iminocyclopropene (4), the iminium derivative (3), and triafulvenes (5–7), with butadiene (Bd) (Scheme 3).

2. COMPUTATIONAL METHODS

Computations were carried out with Gaussian 09, revision D.01.⁷ Geometry optimizations and vibrational frequency calculations were performed using the M06-2X⁸ density functional with the 6-31+G(d) basis set. Single-point energies were calculated at the M06-2X/6-311++G(d,p) level of theory. The M06-2X functional has been shown to

provide relatively accurate energies for cycloadditions.⁹ Solvation effects of dichloromethane (DCM) were included in the optimizations and single-point energies using the self-consistent reaction field (SCRF) using the CPCM model.¹⁰ Normal mode analysis was used to verify each stationary point as either a first-order saddle point or a minimum. The thermal corrections were computed from unscaled M06-2X/6-31+G(d) frequencies for a 1 M standard state and 298.15 K. Truhlar's quasiharmonic correction was applied by setting all positive frequencies below 100 cm^{−1} to 100 cm^{−1}.¹¹ The molecular orbital coefficients from the outer Gaussian function charges were calculated from natural bond orbital (NBO) analysis at the HF/6-31G(d)//CPCM-(DCM)-M06-2X/6-31+G(d) level of theory.¹²

Insight into the origins of the *endo* and *exo* stereoselectivity was provided by the distortion/interaction–activation strain model (D/I-ASM).¹³ This analysis was performed using the ADF.2016.102 program¹⁴ at the M06-2X/TZ2P^{8,15} level of theory on the geometries optimized at CPCM-(DCM)-M06-2X/6-31+G(d) in Gaussian 09. In this framework, the potential energy surface in solution $\Delta E_{\text{solution}}(\zeta)$ is decomposed along the reaction coordinate ζ into the energy of the solute $\Delta E_{\text{solute}}(\zeta)$, specifically the reaction system in vacuum with the solution phase geometry, plus the solvation energy $\Delta E_{\text{solvation}}(\zeta)$.¹⁶

$$\Delta E_{\text{solution}}(\zeta) = \Delta E_{\text{solute}}(\zeta) + \Delta E_{\text{solvation}}(\zeta) \quad (1)$$

Next, the intrinsic energy of the solute $\Delta E_{\text{solute}}(\zeta)$ is separated into the strain $\Delta E_{\text{strain}}(\zeta)$ associated with deforming the individual solute reactants, plus the interaction $\Delta E_{\text{int}}(\zeta)$ between the deformed solute reactants.

$$\Delta E_{\text{solute}}(\zeta) = \Delta E_{\text{strain}}(\zeta) + \Delta E_{\text{int}}(\zeta) \quad (2)$$

The $\Delta E_{\text{int}}(\zeta)$ between the reactants is further analyzed by an energy decomposition analysis (EDA) in the conceptual framework provided by the Kohn–Sham molecular orbital (KS-MO) model¹⁷ and is decomposed into three physically meaningful terms:

$$\Delta E_{\text{int}}(\zeta) = \Delta V_{\text{elstat}}(\zeta) + \Delta E_{\text{pauli}}(\zeta) + \Delta E_{\text{oi}}(\zeta) \quad (3)$$

The $\Delta V_{\text{elstat}}(\zeta)$ term corresponds to the classical electrostatic interaction between unperturbed charge distributions, $\Delta E_{\text{pauli}}(\zeta)$ is responsible for any steric repulsion, and the $\Delta E_{\text{oi}}(\zeta)$ accounts for charge transfer (HOMO–LUMO interactions) and polarization.

3. RESULTS AND DISCUSSION

Figure 1 shows the *endo* and *exo* transition states for the Diels–Alder reactions of butadiene (**Bd**) with triafulvenes (**1–7**). The computed activation free energies ($\Delta G^\ddagger$) are shown below each structure, in kcal/mol. For the *endo* and *exo* Diels–Alder reactions with **Bd**, the activation free energies are in the range 21–29 and 20–27 kcal/mol, respectively. The stereoselectivities of the triafulvene cycloadditions range from a 1.8 kcal/mol *exo* preference to a 2.8 kcal/mol *endo* preference. The cycloaddition of **Bd** with cyclopropenone (**1**) favors the *exo* approach by 1.8 kcal/mol, whereas the 3-difluoromethylene triafulvene (**7**) cycloaddition favors the *endo* reaction by 2.8 kcal/mol. The

Figure 2. Isodesmic equation relating the stability of substituted cyclopropenes (trialfulvenes) to substituted cyclopropanes with the computed reaction enthalpies (ΔH_{ASE}) of trialfulvenes 1–7 in the above isodesmic equation.

activation free energies for neutral trialfulvene analogs range from 21.8 to 28.6 and from 24.4 to 26.8 in the *endo* and *exo* reactions, respectively. The activation free energies for the positively charged iminium cyclopropene (3) with a low lying lowest unoccupied molecular orbital (LUMO) energy are 20.5 and 19.5 for the *endo* and *exo* transition states, respectively.

The effect of each exocyclic cyclopropene group on the stability of 1–7 was assessed using the isodesmic reaction shown in Figure 2, which relates the stability of the trialfulvene to a similarly substituted cyclopropane. All of the groups stabilize the cyclopropene to a greater extent than they stabilize the cyclopropane. We call this aromatic stabilization energy (ASE) since the substituted cyclopropanes have cyclic, potentially aromatic conjugation in the three-membered ring. A more positive number represents greater stability of the substituted cyclopropene compared to the substituted cyclopropane. Schleyer has shown that effects of resonance and hyperconjugation are also included in this isodesmic equation.¹⁸ The substituents have a strong influence on the stability of the cyclopropene. For trialfulvenes 1–7, the calculated aromatic stabilization enthalpies (ASE) are all stabilizing and range from 4.2 to 26.2 kcal/mol. The variation in stabilization arises primarily from differences in the aromaticity of the unsaturated three-membered ring. Electronegative substituents polarize the exocyclic double bond away from the cyclopropene ring, which

causes the cyclopropene rings of these compounds to more closely resemble the 2π electron aromatic cyclopropenyl cation. The π -donor F destabilizes the trialfulvene motif by increasing the four-electron character, thus decreasing the aromatic character of the cyclopropene ring.

The Diels–Alder reactions of **Bd** with cyclopropenes (1–7) are exergonic by –41 to –63 kcal/mol. Consistent with the Hammond postulate, the timing of the transition structures generally becomes earlier as the reaction is more exergonic. As shown in Figure 3a, there is no correlation between the activation enthalpies and the aromatic stabilization enthalpies (2, 3, and 5 are outliers). Figure 3b shows that there is a linear correlation between the exothermicity of reaction (ΔH_{rxn}) and the aromatic stabilization energy of the trialfulvene. The substituents have a significant effect on the reaction free energy, by stabilizing the reactants, but have little effect on the product or on the activation energies.

Application of the distortion/interaction–activation strain model (D/I-ASM) provided quantitative insight into the origins of the reactivity differences and *endo* and *exo* stereoselectivity.¹³ Figure 4a shows the results of our analysis for the *endo* (black) and *exo* (red) Diels–Alder reactions of **Bd** with 3-difluoromethylene trialfulvene (7). The strain, or distortion, curves are nearly identical along the respective reaction coordinates, and the *endo* selectivity is a result of the differences in the interaction energies. Figure 4b shows the decomposition of the interaction energy for the *endo* (black) and *exo* (red) Diels–Alder reactions of **Bd** with 7 along the reaction coordinate. The Pauli repulsion and electrostatic terms are nearly identical along the reaction coordinate. The differences in the strength of the orbital interactions in the *endo* and *exo* reactions are responsible for the *endo* Diels–Alder stereoselectivity of 7.

The results from the distortion/interaction–activation strain model along the reaction coordinate for the *endo* (black) and *exo* (red) Diels–Alder reactions of **Bd** with cyclopropenone (1) are shown in Figure 5a. The strain curves are nearly identical for the *endo* and *exo* reactions, and the *exo* stereoselectivity results from differences in interaction energies. Figure 5b shows the

Figure 3. (a) Plot of the activation enthalpies ($\Delta H^\ddagger$) of the Diels–Alder reactions of 1–7 with butadiene (**Bd**) versus the aromatic stabilization enthalpies (ΔH_{ASE}) (blue *endo*, red *exo*). (b) Plot of the reaction enthalpies (ΔH_{rxn}) versus the aromatic stabilization enthalpies (ΔH_{ASE}) for the Diels–Alder reactions of 1–7 with butadiene (**Bd**) ($\Delta H_{\text{rxn}} = 1.00 \Delta H_{\text{ASE}} - 66.5$, $r^2 = 0.99$).

Figure 6. Sum of charges across the butadiene (**Bd**) atoms, charge at the C₃ position of the triafulvene, and the C₃ p-orbital coefficient of the triafulvenes and heteroanalogs HOMO obtained from the *endo* transition state structures for triafulvenes **1**–**7**. Primary orbital interactions and secondary orbital interactions are represented by blue and red lines, respectively.

decomposition of the interaction energies into the electrostatic, Pauli repulsion and orbital components along the IRC. The *exo* selectivity of cyclopropenone (**1**) results from the combination of the electrostatic and orbital interactions, which overrule the *endo* preference of the Pauli repulsion and favor the *exo* transition state.

Figure 6 summarizes the NBO charges at the C₃ position of the triafulvene and heteroatom analogs **1**–**7**, along with the sum of charges across all atoms of **Bd**, and the C₃ p-orbital coefficient of the triafulvene HOMO in the *endo* transition states. Secondary

orbital interactions (SOI) involve overlap of the C₂ and C₃ p-orbitals of the **Bd** LUMO with the C₃ p-orbital of the cyclopropene HOMO in the *endo* transition state. The C₃ p-orbital coefficients in the HOMO of **1**–**7** range from 0.0 to 0.26. The charges at the C₃ position of **1**–**7** range from -0.18 to 0.61. Polarization of the exocyclic π -bond diminishes the π -electron density at the C₃ position and weakens the strength of the SOI. 3-Difluoromethylene has the largest p-orbital coefficient and the most negative charge at C₃ and is the most *endo* selective. Cyclopropenone (**1**) with the smallest p-orbital HOMO

coefficient and the strongest positive charge at the C₃ is the most *exo* selective.

We next performed molecular orbital analyses to quantify the contribution of the SOI in the *endo* reactions of 1 and 7 with Bd (Figure 7). The molecular orbital (MO) diagrams and overlaps were calculated at the M06-2X/TZ2P//CPCM-(DCM)-M06-2X/6-31+g(d) level of theory by using Kohn–Sham¹⁹ MO analyses on the geometries at C...C bond forming distances of 2.24 Å. In the Diels–Alder reaction of 7 with Bd, the FMO energy gap ($\Delta\epsilon = 6.3$ eV) and the orbital overlap ($S = 0.25$) of HOMO(Bd)–LUMO(7) interaction are the same for the *endo* and *exo* transition states. The HOMO(7)–LUMO(Bd) interaction includes the effects of the SOIs in the *endo* transition

Figure 10. Plot of the stereoselectivities measured as the difference in the activation free energies ($\Delta\Delta G^\ddagger$) between the *endo* and *exo* Diels–Alder reactions of triafulvenes 1–7 with butadiene (Bd) versus the computed NBO charge at C₃ in the triafulvene ground state.

state. The HOMO(7)–LUMO(Bd) of the *endo* and *exo* transition states both exhibit gaps with $\Delta\epsilon = 6.4$ eV. The orbital overlap of the HOMO(7)–LUMO(Bd) in the *endo* transition state ($S = 0.17$) is significantly greater than that in the *exo* transition state ($S = 0.11$), a result of the SOI that arises from the

Figure 11. (a) Distortion/interaction–activation strain analyses and (b) energy decomposition analyses for the *endo* (black) and *exo* (red) Diels–Alder reactions of butadiene (**Bd**) with cyclopropenethione (**2**).

overlap of the p-orbital at the C₃ position in the HOMO of **7** with the C₂ and C₃ p-orbitals in the LUMO of **Bd** in the *endo* transition state.

The reaction between **Bd** and **1** proceeds primarily through a normal electron-demand Diels–Alder cycloaddition, where the key FMO interaction is between the HOMO(**Bd**)–LUMO(**1**) with an FMO energy gap of 6.3 eV for both the *endo* and *exo* approach (Figure 8). The orbital overlaps are similar for the *endo* and *exo* approach with overlaps of 0.24 and 0.25, respectively. The lower lying HOMO–1(**1**) interacts with the LUMO(**Bd**); however, this interaction has a relatively large energy gap of 9.1 eV for both the *endo* and *exo* cycloadditions. The orbital overlaps for the *endo* and *exo* approach are similar at 0.16 and 0.15, respectively. Similar orbital overlap of the HOMO–1 of **1** with the LUMO of **Bd** in the *endo* and *exo* transition state is evidence of weak secondary orbital interactions in the *endo* transition state. The weak SOIs with **1** are a result of the poor overlap between the small p-orbital coefficient at the C₃ position in the HOMO of **1** with the p-orbitals of the newly forming π -bond in the LUMO of **Bd**. Weak SOI explains why the *endo* selectivity disappears from **7** to **1**, but does not explain why cyclopropenone is *exo* selective.

The charge transfer between the triafulvene and **Bd** also appears in the orbital interaction term. The charge at the C₃ position of the triafulvene and heteroatom analogs **1–7** ranges from –0.18 to 0.61 in the *endo* transition states (Figure 6). The reactions are normal electron-demand Diels–Alder reactions, and **Bd** becomes partially positively charged as a result of charge transfer to the dienophile. The magnitude of the charge transfer generally increases as the dienophile becomes more electron-deficient. The sum of charge across all the atoms of **Bd** ranges from 0.05 to 0.22 in the *endo* transition states of **1–7**. Figure 9 shows a qualitative representation of a charge transfer interaction between the C₃ position of the triafulvene and **Bd** in the *endo* transition states. The charge transfer in the *endo* transition state can be understood as being more stabilizing when the C₃ carbon is negatively charged and destabilizing when the C₃ carbon is positively charged. Due to the increased distance between the C₃ position and the diene, this interaction is much weaker in the *exo* transition state. The lack of secondary orbital interactions and the unfavorable charge transfer between the electropositive **Bd** fragment and the electropositive C₃ position of cyclopropenone (**1**) in the *endo* transition state explains why there is a preference

for the *exo* transition state in the Diels–Alder reaction of **Bd** with cyclopropene (**1**).

We have previously shown that both secondary orbital and electrostatic interactions play a role in determining the *endo* and *exo* Diels–Alder stereoselectivity in reactions of 3-substituted cyclopropenes.^{5b} The charge at the C₃ position of the cyclopropene correlates with the cyclopropene stereoselectivity in the absence of steric effects and serves as a useful way to predict the stereoselectivity of cyclopropene Diels–Alder reactions. Figure 10 shows a linear correlation between the stereoselectivity ($\Delta G_{\text{endo}}^{\ddagger} - \Delta G_{\text{exo}}^{\ddagger}$) and the NBO charge at the C₃ position of the triafulvene for the Diels–Alder reactions of triafulvenes **1–7** with **Bd**. The stereoselectivity increases linearly with increasing positive charge at the C₃ position of **1–7** with cyclopropenethione **2**, an obvious outlier, represented by the unfilled diamond.

The π -densities and charges at the C₃ positions are determined by the polarization of the exocyclic double bond. Compared to the C=O double bond of cyclopropenone (**1**), the C=S double bond of the cyclopropenethione (**2**) is less polarized because of the smaller difference in the electronegativities of carbon and sulfur compared to that of carbon and oxygen. However, sulfur is a strong π acceptor, and because of its size, it can accommodate additional π -electron density compared to oxygen. Theoretical studies by Wiberg et al. found that the π -densities of the C=O bond in cyclopropenone and the C=S bond in cyclopropenethione are similar, despite the differences in the polarization of the C=S of C=O bonds.²⁰ This is consistent with **1** and **2** having similarly small HOMO orbital coefficients at the C₃ carbon, but different charges at the C₃ carbon (see Figure 6).

Figure 11 shows the distortion/interaction–activation strain and energy decomposition analyses for the *endo* and *exo* Diels–Alder reaction of **Bd** with cyclopropenethione (**2**). The slightly *exo* stereoselectivity in the Diels–Alder reaction of **Bd** with **2** results from poor stabilization of the *endo* transition state through secondary orbital and electrostatic interactions.

4. CONCLUSIONS

The reactivities and stereoselectivities of Diels–Alder reactions of cyclopropenone and triafulvene analogs are controlled by both the charge and HOMO coefficient at the C₃ carbon. In the *endo* transition state, polarization of the exocyclic bond by electron-

withdrawing groups weakens the strength of the stabilizing secondary orbital interactions and creates unfavorable charge transfer between the electropositive C₃ position of the triafulvene and butadiene that favors *exo* stereoselectivity. The Diels–Alder reactivities of the triafulvene and heteroanalogs decrease as the size of the HOMO coefficient at the C₃ carbon decreases as a result of weaker secondary orbital and charge transfer interactions. We predict that *exo* stereoselectivity is favored when the exocyclic triafulvene group is O, S, or NR₂⁺, *endo* stereoselectivity when CR₂ is the exocyclic group, and poor stereoselectivity when NR is the exocyclic substituent.
