CHAPTER 2

REV7 counteracts DNA double-strand break resection and impacts PARP inhibition

*These authors contributed equally to this work.

Abstract

Error-free repair of DNA double-strand breaks (DSB) is achieved by homologous recombination (HR), and BRCA1 is an important factor for this repair pathway\(^1\). In the absence of BRCA1-mediated HR, administration of PARP inhibitors induces synthetic lethality of tumor cells of patients with breast or ovarian cancers\(^2,3\). Despite the benefit of this tailored therapy, drug resistance can occur by HR restoration\(^4\). Genetic reversion of BRCA1-inactivating mutations can be the underlying mechanism of drug resistance, but this does not explain resistance in all cases\(^5\). In particular, little is known about BRCA1-independent restoration of HR. Here, we show that loss of REV7 (also known as MAD2L2) in human and mouse cell lines re-establishes CtIP-dependent end resection of DSBs in BRCA1-deficient cells, leading to HR restoration and PARP inhibitor resistance, reversed by ATM kinase inhibition. REV7 is recruited to DSBs in a manner dependent on the H2AX-MDC1-RNF8-RNF168-53BP1 chromatin pathway, and appears to block HR and promote end joining in addition to its regulatory role in DNA damage tolerance\(^6\). Finally, we establish that REV7 blocks DSB resection to promote non-homologous end-joining (NHEJ) during immunoglobulin class switch recombination. Our results reveal an unexpected critical function of REV7 downstream of 53BP1 in coordinating pathological DSB repair pathway choices in BRCA1-deficient cells.
To identify mechanisms of BRCA1-independent restoration of the HR pathway, we carried out a loss-of-function shRNA screen using the KB1P-B11 and KB1P-G3 cell lines that we previously derived from Brca1^−/−;p53^−/− (p53 is also known as Trp53) mouse mammary tumors\textsuperscript{7} (Fig. 1a and online Table 1: http://www.nature.com/nature/journal/v521/n7553/extref/nature14328-s1.xls).

Cells with HR restoration were selected with a high concentration of olaparib (500 nM, about 100-fold the IC\textsubscript{50}), which killed cells of the empty vector control. Sequencing of the olaparib-surviving colonies revealed a reproducible enrichment of various individual hairpins targeting Rev7 or 53bp1. To validate the Rev7 hit, we introduced 2 different hairpins into the B11 and G3 cell lines; these substantially inhibited Rev7 expression (Fig. 1b, c and Extended Data Fig. 1a). Despite the role of REV7 in metaphase-to-anaphase transition\textsuperscript{8}, the level of Rev7 inhibition in these cells did not affect proliferation (Extended Data Fig. 1b, c), allowing long-term clonogenic survival assays. We confirmed that loss of Rev7 resulted in increased resistance to the PARP inhibitors (PARPi) olaparib and AZD2461\textsuperscript{7} in both cell lines (Fig. 1d and Extended Data Fig. 1d-g). Resistant cells that survived olaparib treatment (Rev7-sh#-ola) yielded even lower REV7 expression levels and increased numbers of colonies after PARPi treatment (Fig. 1b-d and Extended Data Fig. 1h). When we reconstituted the Rev7-depleted cells with shRNA-resistant Rev7 cDNA resulting in similar REV7 protein levels (Extended Data Fig. 1i), we successfully re-sensitized the tumor cells to PARPi (Fig. 1e, f).

Tumors derived from the Brca1^−/−;p53^−/− cells with stable Rev7 inhibition also showed olaparib resistance \textit{in vivo}, in contrast to the empty vector controls (Fig.1g and Extended Data Fig. 1j-l). In addition, we found that Rev7 loss explains some cases of \textit{in vivo} acquired PARPi resistance in BRCA1-deficient mouse mammary tumors (data not shown). REV7 depletion also resulted in PARPi resistance of the human BRCA1-deficient cell line SUM149PT (Extended Data Fig. 2). Together, these data strongly indicate that inhibition of Rev7 confers PARPi resistance in BRCA1-deficient tumor cells.

Together with the catalytic subunit REV3, REV7 forms the translesion synthesis (TLS) polymerase ζ (Polζ), and it interacts with REV1\textsuperscript{9}. We therefore
investigated whether REV1 or REV3 loss also confers PARPi resistance in \( Brca1^{-/-};p53^{-/-} \) cells. A 60% inhibition of Rev1 or Rev3 transcripts did not cause olaparib resistance (Extended Data Fig. 3a-d). Moreover, we studied various shRNA-resistant REV7 mutants that lack REV1 (L186A/Q200A/Y202A and 1-183aa) or REV3 (C70R) binding sites\(^{10,11}\). In contrast to the truncated 1-140 aa REV7 protein, these mutants are recruited to DNA damage sites (Extended Data Fig. 3e-g) and their expression in KB1P-B11-shRev7 and KB1P-G3-shRev7 cells significantly restored the sensitivity to PARPi to a degree approaching that of wild-type REV7 (Fig. 2a, b; \( P<0.001 \), t-test). The remaining differences of the L186A/Q200A/Y202A or C70R mutants with wild-type REV7 may be explained by unequal expression levels (Extended Data Fig. 3f). These data suggest that the REV1 or REV3 interaction is not absolutely required for the REV7-mediated function in this context.

We observed that GFP-tagged REV7 co-localizes with 53BP1 shortly after DNA damage induction, suggesting that REV7 acts directly at the site of DNA damage (Fig. 2c). REV7 recruitment depends on H2AX, MDC1, RNF8, RNF168, and partly ATM, in both mouse and human cells (Fig. 2d, e and Extended Data Fig.4a-d). To examine whether PARPi resistance in \( Rev7^{-/-} \) depleted \( Brca1^{-/-};p53^{-/-} \) tumor cells is due to HR restoration, we investigated RAD51 focus formation after 10 Gy IR. As shown in Fig. 3a, b and Extended Data Fig. 4e, f, \( Rev7 \) loss resulted in the restoration of RAD51 foci formed following DNA damage. To exclude potential off-target effects of the hairpins, we reconstituted shRev7#1+2 cells with shRNA-resistant mouse or human REV7-GFP fusion proteins (Extended Data Fig. 4g). REV7 re-expression abolished RAD51 focus formation upon DNA damage in GFP-positive cells (Fig. 3b). We confirmed the re-appearance of RAD51 foci upon tumor irradiation \( in vivo \) using computed tomography (CT)-guided high precision cone beam irradiation of animals carrying PARPi-resistant KB1P(M) tumors with low \( Rev7 \) gene expression (Fig. 3c).

We then tested whether the processing of broken DNA ends requires ATM in \( Rev7^{-/-} \) depleted cells, and found that inhibition of ATM using KU55933 efficiently suppresses DNA damage-induced RAD51 foci and increases olaparib sensitivity (Extended Data Fig. 4h, i). Hence, the partial restoration of RAD51
focus formation in Brca1-deficient mammary tumor cells upon DNA damage by inhibition of Rev7 is ATM-dependent.

In contrast to the results with BRCA1-deficient cells, Rev7 depletion in BRCA2-deficient cells did not result in PARPi resistance (Extended Data Fig. 5a-f). Furthermore, we did not observe increased PARPi resistance following Rev7 inhibition in the BRCA1/2-proficient p53−/− tumor cell line KP3.33 (Extended Data Fig. 5g-i). This indicates that REV7 works upstream of BRCA2 and is antagonized by BRCA1. We therefore tested whether DNA end resection is altered in the absence of Rev7 in BRCA1-deficient cells. Accumulation of the single-strand binding protein, RPA, was employed as a marker for the generation of ssDNA. Cells were exposed to alpha particles, and BRCA1 deficiency resulted in a marked decrease in RPA-positive alpha tracks compared to BRCA1-proficient cells (Fig. 3d, e). REV7 depletion in the Brca1−/−;p53−/− cells largely suppressed this defect in both KB1P-G3 and KB1P-B11 cells (Fig. 3e and Extended Data Fig. 6a). In addition to coating resected DNA ends, RPA also interacts with ssDNA gaps (e.g. during replication). To exclude that the observed RPA accumulation reflected interaction with internal ssDNA gaps, we prevented DNA end resection (without influencing replication) by knocking down CtIP. This eliminated the increase in RPA-positive tracks induced by Rev7 knockdown in Brca1−/−;p53−/− cell lines (Fig. 3f and Extended Data Fig. 6b), without affecting cell cycle distribution (Extended Data Fig. 6c). We therefore conclude that increased resection and not binding to ssDNA gaps is responsible for RPA accumulation.

As Rev7 loss could restore end resection in BRCA1-deficient cells, we analyzed whether its depletion could restore full HR proficiency in this context. Using mES cells with a Brca1 selectable conditional knockout allele, we observed that Rev7 loss indeed prevented cell death of mES cells upon BRCA1 deletion and restored RAD51 focus formation upon DNA damage (Extended Data Fig. 6d-h). Moreover, we reproducibly observed a partial restoration of HR function in the DR-GFP reporter assay for homologous recombination when Rev7 was depleted in BRCA1-deficient mES cells (Fig. 3g).

Our data for REV7 are reminiscent of previous findings that 53BP1 loss occurs in subsets of human breast carcinomas and can also restore HR to
BRCA1-deficient cells\textsuperscript{7,15,17}. As with 53BP1, we found a frequent aberrant reduction or loss of the REV7 protein in human triple-negative breast carcinomas (Extended Data Fig. 7). Addressing the relationship between REV7, 53BP1 and 53BP1’s NHEJ effector protein, RIF1\textsuperscript{18}, we found that Rev7 deficiency did not compromise the formation of endogenous 53BP1 or RIF1 foci (Extended Data Fig. 8a-d). In contrast, endogenous REV7 foci or laser-induced stripes were absent in 53BP1-depleted mouse and human cells (Figure 4a and Extended Data Fig. 4c, d), strongly suggesting that REV7 acts downstream of 53BP1. This is also consistent with our results that PARPi resistance is not increased when both Rev7 and 53bp1 are depleted (data not shown). Despite such strong evidence for a cooperative role for REV7 and 53BP1, we did not detect REV7 in 53BP1 immunocomplexes isolated from untreated cell lysates, or ATM-phosphorylated 53BP1 immunocomplexes containing RIF1 that were induced by DNA damage\textsuperscript{19} (Extended Data Fig. 8e and data not shown). Although the intricacies of the interactions remain to be determined, REV7 recruitment to DNA damage sites by 53BP1 may result from indirect interactions or an activity elicited by 53BP1 protein complexes in chromatin at DSB sites.

To examine whether REV7, like 53BP1\textsuperscript{18}, also promotes NHEJ of DSBs during class switch recombination (CSR), we depleted Rev7 transcripts in the murine CH12 B-cell line, which upon stimulation undergoes CSR from IgM to IgA at a high rate\textsuperscript{20}. Efficient Rev7 knockdown was achieved using multiple shRNAs, reducing CSR to levels comparable with 53BP1-depleted cells when compared to control-depleted cells (Fig. 4b and Extended Data Fig. 9a, b). Moreover, these defects were not accompanied by defects in cell proliferation, AID (Aicda), or germline transcript (μGLT/αGLT) expression (Extended Data Fig. 9c-e). Conditional REV3-ablation has been reported to reduce CSR efficiency in B lymphocytes\textsuperscript{21}, suggesting that distinct from 53BP1, REV7 might participate in CSR through Pol ζ function. This considered, we reasoned we might separate the function of REV7 from that of Pol ζ during CSR, at the level of DSB resection inhibition. To this end, RPA enrichment was measured by chromatin immunoprecipitation (ChIP) at control and multiple IgH loci in control, 53BP1-, REV3- or REV7-depleted CH12 lines stimulated to undergo CSR. Consistent with 53BP1’s role in resection inhibition, 53BP1-depletion was accompanied by
3- to 5-fold enrichment of RPA ChIP signal specifically in donor (Sµ) and acceptor (Sa) IgH switch (S) regions where DSBs occur during IgM to IgA CSR, but not at an IgH Sy1 locus or a control non-IgH Rpp30 locus (Fig. 4c). Strikingly, these defects were closely mimicked upon REV7-depletion, while shRNA mediated REV3-depletion yielded no detectable increase in RPA IgH S-region enrichment, despite diminishing CSR efficiency (Extended Data Fig. 9f) as expected\(^2\). Importantly, at each locus equivalent ChIP signals for total histone were obtained between cell-lines. Thus, our data support a Pol \(\zeta\)-independent function of REV7 in inhibiting the nucleolytic processing of DSBs generated during CSR.

Our data uncover a critical role for REV7 in regulating DSB repair. REV7 depletion restores homology-directed DNA repair of BRCA1-deficient cells resulting in PARPi resistance. We attribute this result to the inhibitory effect of REV7 on DNA end resection. Like 53BP1 together with RIF1 and PTIP\(^1\), REV7 may function as a NHEJ factor that performs a regulatory role in DSB repair pathway choice. This provides new insight into the versatile functions of REV7 in addition to its role in translesion synthesis\(^9,22\), and helps to explain how HR can be partially restored in the absence of BRCA1.

METHODS
Cell culture and reagents
KB1P_B11 (B11) and KB1P_G3 (G3) cell lines were derived from a Brca1−/−;p53−/− mouse mammary tumor as described7. KB2P_1.21 and KB2P_3.4 cell lines originate from a Brca2−/−;p53−/− mouse mammary tumor and KP3.33 cell line from a p53−/− mouse mammary23. These cell lines were cultured in DMEM/F-12 (Life Technologies) supplemented with 10% FCS, 50 U/mL penicillin, 50 ng/mL streptomycin, 5 µg/mL insulin (Sigma), 5 ng/mL epidermal growth factor (Life Technologies) and 5 ng/mL cholera toxin (Gentaur) under low oxygen conditions (3% O2, 5% CO2, 37°C). SUM149PT cells were grown in RPMI1640 (Life Technologies) supplemented with 10% FCS, under normal oxygen conditions (21% O2, 5% CO2, 37 °C). U2OS, phoenix, 293T cells were cultured in DMEM (Life Technologies) supplemented with 10% FCS, under normal oxygen conditions (21% O2, 5% CO2, 37 °C). Mouse ES cells with a selectable conditional BRCA1 deletion (R26CreERT2/wt;Brca1Sc/o)15 were cultured on gelatin-coated plates in 60% buffalo red liver (BRL) cell conditioned medium supplied with 10% fetal calf serum, 0.1 mM β-mercaptoethanol (Merck) and 10^3 U/ml ESGRO LIF (Millipore) under normal oxygen conditions (21% O2, 5% CO2, 37 °C). CH12 cells (CH12F3-2) were cultured in RPMI-1640 medium (Sigma) supplemented with 10% FBS, 5% NCTC 109 medium (Sigma), 50 µM β-mercaptopoethanol, 50 U/mL penicillin and 50 ng/mL streptomycin under normal oxygen conditions. Olaparib and AZD2461 were provided by AstraZeneca; KU-55933 (KuDOS) was bought from Selleckchem (S1092).
**Lentivirus-based transduction of cells with shRNA**

Glycerol stocks of shRNA hairpins were obtained from the Sigma Mission library (TRC 1.0) and isolation of plasmids was carried out with the high pure plasmid Mini Kit or Genopure maxi kit (Roche). 293T cells were seeded 16 h prior to transfection. For each 10 cm dish, 0.5 mL 2x HBS (8.18 g NaCl, 0.2 g Na$_2$HPO$_4$·7H$_2$O, 5.95 g HEPES in 500 ml MilliQ water at pH 7.01) was added into a sterile falcon tube. In another sterile falcon tube, 6 µg plasmid DNA of interest, 2 µg pHCMV-G envelope vector (pMD.G), 2 µg pRSV-Rev, 2 µg packaging vector pMDLG/pRRE, 250 µl 0.5 M CaCl$_2$ and distilled water were added to bring up to 0.5 mL. The CaCl$_2$/plasmid DNA mix was added to the 2x HBS and incubated for 20 min and then added to the cells. Medium was refreshed after 6 h and another 18 h, respectively. The supernatant of 293T cells containing lentivirus was collected after 24 h to infect cells with polybrene (6 µg/mL) for 12 h. The medium was refreshed after lentivirus infection and the cells were selected with puromycin.

Individual shRNA vectors used were collected from the TRC library.

**Loss-of-function screen**

1976 lentiviral hairpins (pLKO.1) from the Sigma Mission library (TRC Mm 1.0) which target 391 mouse genes involved in the DNA damage response were selected (see Supplementary Table 1). This library was used to generate pools of lentiviral shRNA in 293T cells to infect target cells. After infection, the cells stably expressing integrated shRNA were selected with puromycin. Cells with HR restoration were selected with a high concentration of olaparib (500 nM, about 100-fold the IC\textsubscript{50}) which killed cells of the empty vector group. Surviving cells were pooled and genomic DNA was extracted using the Gentra Puregene kit according to the manufacturer’s protocol (Qiagen). ShRNA inserts were retrieved from 50 ng genomic DNA by PCR amplification (PCR1 and PCR2) using the following conditions: (1) 95 °C, 5 min; (2) 95 °C, 30 s; (3) 60 °C, 30s; (4) 72 °C, 1 min; (5) Go to step (2), 20 cycles; (6) 72 °C, 5 min; (7) 4 °C. The PCR reaction system were as follows: 0.6 μL DMSO, 4.0 μL phusion HF buffer 5x, 0.4 μL dNTPs, 1.0 μL primer f (10 mM), 1.0 μL primer r (10 mM), 11.8 μL mQ, 0.2 μL phusion,1.0 μL gDNA for PCR1 or 1 μL PCR1 products for PCR2.Adaptors and Indexes for deep sequencing (Illumina HiSeq 2000) were incorporated into PCR primers as follows:

PCR2 products were purified using the PCR purification Kit from Qiagen. The
shRNA stem sequence was segregated and aligned to the TRC library. The
reads of different hairpins were counted and the following criteria were used to
select the top hits for further validation: first, hairpins targeting the same gene in
survival clones should have at least10^4 reads (total ~6x10^6 reads); second, at
least 2 different hairpins targeting the same gene should be present; third,
hairpins in resistant clones should be highly enriched (>8-fold) in cells after
olaparib selection; fourth, hairpins should be present in 4/4 independent
screens.
PARPi treatment study

Long-term clonogenic assay: on d0, 1.5x10^4 (B11) or 1x10^4 (G3, KB2P_1.21 or KB2P_3.4) or 6x10^3 (KP3.33) cells were seeded per well with PARPi (or untreated control) into 6-well plates. The medium of the PARPi treatment groups was refreshed with PARPi every 4 d. On d5, the untreated control group was stopped and the PARPi treatment groups were stopped after another 2 to 3 weeks and stained with 0.1% crystal violet. Using the SUM149PT cells, 4x10^4 cells were seeded per well with olaparib (or untreated control) into 12-well plates. The medium of the PARPi treatment groups was refreshed with olaparib every 4 d. On d6, the untreated control group was stopped and the olaparib treatment groups were stopped on d8 and stained with 0.1% crystal violet. Quantification of the clonogenic assay was done by determining the absorbance of crystal violet at 590 nm.

Short-term clonogenic assay: On d0, 4x10^2 (G3) cells were seeded per well with olaparib (or untreated control) into 6-well plates. On d4, the medium was refreshed with olaparib or untreated control. On d8, all the groups were stained with Leishman dye and quantification was done by the relative colony numbers.

ATMi and PARPi combination study

On d0, 1x10^4 (G3) cells were seeded per well into 6-well plates and then ATMi or olaparib or their combination was added. The medium was refreshed every 3 d with the different drugs. For the combination therapy groups, ATMi was applied for 6 d. On d5, ATMi alone and untreated control groups were stopped and the other groups were stopped on d12 and stained with 0.1% crystal violet.

Constructs

Human REV7 was amplified by PCR using Platinum Taq polymerase (Invitrogen) from U2OS cDNA using the following primers 5’-ATAGAATTCAATGACCACGCTCACACGACAAGAC-3’ and 5’-ATATGGTACCATCAGCTGCCTTTATGAGCGCGC-3’. Mouse Rev7 was amplified from mouse lung cDNA in two parts to introduce silent mutations, making it resistant to Rev7-sh2# (mRev7R). The following primers were used for part A: [IB11m] 5’-ATATGAATTCCGATGACCACCTACGACGCGC-3’ [IB14m] 5’-
TACCCTTTCCGTTTCTGAAAGATGCCACCCGGGTA-3' and part B: [IB12m] 5'-ATATGGTACC-AT-GCTGTTCTTATGCCTCGCT-3' and part B: [IB12m] 5'-GGGCATCTTTCAGAAGCGGAAGGTCAACGTGC-3'. Equal parts of both PCR reactions were mixed and used for a PCR using IB11m and IB12m to create the complete mouse Rev7 sequence including the silent mutations. The PCR product and pEGFP-C1 vector were digested using EcoRI and KpnI and ligated using the T4 DNA Ligase (Roche) to generate pEGFP-hRev7 and pEGFP-mRev7R.

Using pEGFP-mRev7R as a template, pEGFP-C1 based Rev7 truncated constructs was amplified by PCR using the following primers:
Forward primer: 5'-ATAT-GAATTC-GATGACCACCCTCACGC-3'.
Reverse primers:
mRev7R (1-55aa): 5'-ATAT-GGTACC-GGACATCTGAAACCGCAG -3';
mRev7R (1-81aa): 5'-ATAT-GGTACC-CTCCATCGTTCTCTCCAGG -3';
mRev7R (1-110aa): 5'-ATAT-GGTACC-GATGGACAGCAAGGAGGC -3';
mRev7R (1-140aa): 5'-ATAT-GGTACC-GTTGTGATCCAGGACAGC -3';
mRev7R (1-183aa): 5'-ATAT-GGTACC-GTCGTGACATGTTGAGACATCCTG-3'.

pEGFP-Rev7 mutants (shRNA resistant) were ordered as gBlocks (IDT) and cloned into the pEGFP-C1 vector using EcoRI and KpnI restriction enzymes and quick ligase (NEB). The DNA sequences that were ordered as gBlocks are:

mRev7_shRNAresistant(mRev7R):

PCR products were purified using PCR purification kit (Roche) and then subjected to BP (BP-clonase II, Invitrogen) and LR (LR-clonase II, Invitrogen) reaction according to manufacturer’s instructions. Wt 53BP1 and 53BP120AQ constructs were previously described19. All the constructs were verified by sequencing.

siRNA, cDNA transfection and cDNA transduction
SMARTpool siRNAs targeting mouse CtIP (siGENOME: M-055713-02, Thermo Scientific) and non-targeting control were transfected into cells using DharmacoN1 transfection reagent (Thermo Scientific). After 48 h, cells were subjected to western blot and Alpha track assay. siRNAs against 53BP1, RNF8 or RNF168 were transfected into cells using Lipofectamine RNAiMax according to the manufacturer’s instruction. The sequences of si53BP1: 5’-GAGAGCGAGAGAUGAUCCUUUA-3’; siRNF8: 5’-GGACAAUUUAUGGACAAACAATT-3’; siRNF168: 5’-GGCGAAGAGCGAUGGAGGAtt-3’, siGFP (5’-GGCUACGUCCAGGAGCGCACCTT-3’. Immunofluorescence and western blotting analysis was done 64 h after transfection.

For pEGFP-based constructs, transient transfection was done using X-treme GENE HP DNA transfection reagent (Roche) according to the manufacturer’s
GFP-positive cells were sorted by flow cytometry and subjected to Western blotting and immunofluorescence staining.

For pMSCV-GFP (retrovirus) based constructs, transient transfection was done using X-treme GENE HP DNA transfection reagent in phoenix cells and the medium was refreshed after 24 h. Retroviruses were collected 48 h after transfection and then target cells were infected for two consecutive periods of 12h using fresh virus. The medium was refreshed after retroviruses infection and the cells were selected with blasticidin.

For pLenti6-UBC (lentivirus) based constructs, together with the packaging plasmids p59, p60 and p61, transient transfection was done using X-treme GENE HP DNA transfection reagent in 293T cells and the medium was refreshed after 24 h. Lentiviruses were collected 48 h after transfection and then target cells were infected for two consecutive periods of 12h using fresh virus. The medium was refreshed after lentivirus infection and the cells were selected with blasticidin.

Mice, generation of PARPi-resistant mouse mammary tumors
All mouse experiments were approved by the Animal Experiments Review Board of the Netherlands Cancer Institute (Amsterdam), complying with Dutch legislation. Olaparib-resistant KB1PM- and AZD2461-resistant KB1P mouse mammary tumors were generated as described\(^7\). In this study we analyzed a total of 55 PARPi-resistant and 52 PARPi-sensitive tumors derived from 13 individual KB1PM and 10 individual KB1P donor tumors.

To generate mouse mammary tumors from cell lines, 5x10\(^5\) cells were orthotopically transplanted into 6-wk old female wild-type FVB/N_Ola129 mice as reported previously\(^7\). Mice were randomized to the PARPi or untreated control groups.

RT-qPCR
Total RNA was isolated from cells using the high pure RNA isolation kit (Roche). cDNA was made from 1ug RNA with the GoScript™ Reverse Transcription system (Promega). For the quantitative PCR cDNA, Primer Fw&Rv (400 nM) and Lightcycler 480 SYBR Green I Master (Roche) were applied in a Lightcycler
480 96-well plate (Roche). The SYBR green signals were measured with Lightcycler 480 II (Roche). The Cp value of the gene of interest was subtracted from the housekeeping gene. This value was put in the power of 2 and this was also done for the SD. The primer sequences used in this study are as follows:

**Western blotting**

Cells were washed with ice-cold PBS and lysed on ice for 30 min with RIPA lysis buffer supplemented with three protease inhibitors (P8340, P5726, P0044; Sigma-Aldrich). Protein concentration was determined by the Bradford Protein
Assay Kit (Bio-Rad) and a calibration standard curve created from the BSA. The
samples were prepared for loading by adding 4x sample buffer (Invitrogen) and
heating the samples at 70 °C for 10 min. Total proteins were separated by SDS-
PAGE on 3-8% Tris-acetate (for 53BP, Rif1) or 4-12% Bis-Tris gradient gels (all
others). Next, proteins in the gel were electrophoretically transferred to PVDF
membrane (Millipore) (for REV7, ACTB, α-tubulin) or to NC membranes
(Invitrogen) (all others) and then the membrane was blocked in 5% milk with
Tris-buffered saline Triton X-100 buffer (100 mM Tris, pH 7.4, 500 mM NaCl,
0.1% Triton X-100) (TBS-T0.1%). Membranes were incubated with primary
antibodies in 5% milk in TBS-T0.1% overnight at 4 °C. HRP-conjugated
secondary antibody incubation was performed for 1 h at RT in 5% milk in TBS-
T0.1% and signals were visualized by ECL. Primary antibodies used in this
study were as follows: mouse anti-REV7 (612266, BD Biosciences), 1:5,000
dilution; rabbit anti-53BP1 (NB100-304, Novus), 1:1,000 dilution; rabbit anti-
53BP1 (A300-272A, Bethyl), 1:5,000 dilution; rabbit anti-CtIP (ab70163,
Abcam), 1:1,000 dilution; mouse anti-alpha-tubulin (T6074, Sigma), 1:5,000
dilution; mouse anti-ACTB (MAB1501R, Millipore), 1:5,000 dilution; rabbit anti-
mouse Rif1 (SK1316)19, 1:2,000 dilution; mouse anti-RNF8 (B-2, Santa Cruz),
1:1,000 dilution; rabbit anti-RNF16827, 1:5000 dilution; mouse anti-GAPDH
(1D4, GeneTex) 1:1000 dilution. Secondary antibodies used in this study were
as follows: polyclonal rabbit anti-mouse immunoglobulins/HRP (P0161, Dako),
1:10,000 dilution; polyclonal swine anti-rabbit immunoglobulins/HRP (P0217,
Dako), 1:10,000 dilution.

Immunofluorescence
Cells were grown on glass coverslips (12 mm) in 24-well plates. To induce
Ionizing Radiation-Induced Foci (IRIF), cells were γ-irradiated (10 Gy) and
compared to non-irradiated controls 5 h post-IR. For this purpose the cells were
pre-extracted using cold CSK buffer (10 mM HEPES-KOH pH 7.9, 100 mM
NaCl, 300 mM sucrose, 3 mM MgCl₂, 1 mM EGTA and 0.5% v/v Triton-X100) on
ice for 5 min and then cold CSS buffer (10 mM Tris pH 7.4, 10 mM NaCl, 3 mM
MgCl₂, 1% v/v Tween and 0.5% w/v sodium Deoxycholate) on ice for 5 min.
Cells were washed with PBS++ (PBS with 1 mM CaCl₂ and 0.5 mM MgCl₂) and
fixed using 2% paraformaldehyde (PFA)/PBS++ for 20 min at RT. Fixed cells were washed 3x with PBS++ and stored at 4 °C. The cells were incubated 20 min in 0.2% Triton X-100/PBS++ to be permeabilized. Then the cells were washed 3x in staining buffer (PBS++: 1% BSA, 0.15% glycine, 0.1% Triton X-100), incubated 30 min in staining buffer at RT, incubated with the first antibody for 2h at RT in staining buffer, washed 3x in staining buffer, incubated with the second antibody for 1h at RT in staining buffer and washed 3x in staining buffer. Next, the cells were counter-stained with DAPI for 5 min, washed in staining buffer, washed in PBS++, mounted in Vectashield and sealed with nail polish. Primary antibodies used in this study were as follows: rabbit anti-RAD51 (70-001, BioAcademia), 1:20,000 dilution; rabbit anti-53BP1 (A300-272A, Bethyl), 1:4000 dilution. Secondary antibodies used in this study were as follows: Alexa fluor 568 F(ab')2 Fragment goat anti-rabbit (A21069, Invitrogen), 1:1,000 dilution; Alexa fluor 488 anti-mouse antibody (A11001, Invitrogen), 1:1,000 dilution.

For REV7 staining in MEF cells, cells cultured on coverslips were treated with 10 Gy IR and allowed to recover for 4 h. Cells were then washed with PBS, pre-extracted with 0.5% Triton-X100 solution for 3 min and fixed with 3% paraformaldehyde for 12 min. Coverslips were washed with PBS and then immunostained with Rev7 antibody (612266, BD Biosciences, 1:200 dilution) and anti-γH2AX or anti-53BP1 in 5% goat serum for 1h at RT. Coverslips were washed and incubated with secondary antibodies conjugated with rhodemine or FITC for 30 min at RT. Cells were then stained with DAPI to visualize nuclear DNA. The coverslips were mounted onto glass slides with anti-fade solution. For RIF1 staining in MEF cells, wild-type MEFs stably transduced with indicated shRNA-expressing lentiviruses were examined for RIF1 foci following neocarzinostatin (NCS) treatment. Automated quantification of RIF1 foci following mock and NCS treatment was performed using Cell-Profiler software (Broad Institute).

**Laser irradiation of human cells and Immunofluorescence staining**

Cells were grown on plastic disks (17 mm diameter) which were cut using CNC cutter from the bottom of standard 10 cm cultivation dish (TPP, Switzerland) UV-sterilized and placed inside the wells of a 12-well plate. BrDU (0.5 µM) was
added into siRNA transfected cells 40 h after the transfection to pre-sensitize cells towards UV-A wavelength. Twenty-four hours after BrdU addition the plastic disk with cells were removed and covered by a coverslip and immediately placed inside Zeiss AxioObserver Z.1 inverted microscope combined with LSM 780 confocal module. Cells were irradiated at 20 °C via 40x water immersion objective (Zeiss C-Apo 40x/1.2W DICIII, ) using 355 nm 65 mW laser set on 100% power. The total laser dose which can be further manipulated by the amount of irradiation cycles was empirically set to 6 irradiation cycles. Laser track was pre-defined to cover all the cells within the acquisition area with at least one stripe across the nucleus. After the irradiation process the coverslip was gently removed and plastic disk was quickly placed back into the same well of the 12-well plate and incubated for another 45 min at standard cultivation conditions. The plastic disks with laser-irradiated cells were first processed by pre-extraction at 4°C. It involves washing by PBS (4 °C), equilibration for 2 min in sucrose buffer 1 (10 mM PIPES pH 6.8, 100 mM NaCl, 1.5 mM MgCl₂, 300 mM sucrose) on ice and then pre-extraction for 15 min on ice, on slow-moving shaker using sucrose buffer 2 (10 mM PIPES pH 6.8, 100 mM NaCl, 1.5 mM MgCl₂, 300 mM sucrose, 0.5% Triton-X100, 5 μg/mL leupeptin, 2 μg/mL aprotinin, 0.1 mM PMSF,1 mM DTT). After the pre-extraction cells were washed by PBS (4 °C) and fixed by 4% PAF for 15 min at RT. PAF was washed out 3x by RT PBS. The disks were further processed as standard coverslips (i.e. blocking in blocking solution (D-MEM + 20% fetal serum) for 1 h at RT followed by incubation with primary antibodies involving REV7 (BD Bioscience, mouse, 1:200), pS139-H2AX (Cell Signaling, 20E3, rabbit, 1:300) and 53BP1 (Santa Cruz, H-300, rabbit 1:400) for 2h at RT and with appropriate secondary antibodies coupled to AlexaFluor 488 and AlexaFlour 568 fluorophores (dilution 1:1000) (Life Technologies). Both primary and secondary antibodies were dissolved in the blocking solution. After washes in PBS, the disks were incubated in 1 μg/mL 4′,6-diamidino-2-phenylindole (DAPI) in dH₂O at RT for 5 min and air dried. Dried disks were placed on a standard microscopy glass (cell layer face up) and anchored by two rubber bands laced over the glass. Stained cells were mounted using VectaShield (Vector Labs) mounting medium and covered by coverslip. The samples were examined using Zeiss AxioObserver
Z.1 inverted microscope combined with LSM 780 confocal module using 40x oil objective (Zeiss EC PlnN 40x/1.3 Oil DICII). It means that after the first acquisition the plastic disk and the microscopy glass was marked by diamond cutter (to ensure same positioning of the disk in the future), the coverslip was gently removed and disk was washed 3x by PBS/0.5% Tween to remove the mounting medium. Next, the disk was incubated at RT in the 1x Re-Blot solution (Re-Blot Plus Mild, Millipore) for 30 min on a slow moving shaker. The solution was washed out 3x by RT PBS. Such sample was ready for new staining procedure involving new set of primary and secondary antibodies following the same protocol as described above.

**In situ analysis of RAD51 foci formation**

Five matched PARPi-resistant and -sensitive KB1P(M) tumors were orthotopically transplanted into wild-type FVB/N recipient mice. When tumors reached ~500 mm³ in volume the mice were randomized to be either irradiated (dose: 15 Gy) using a CT-guided high precision cone beam micro-irradiator (XRAD 225Cx) or to be left untreated. As a positive control a BRCA1-proficient KP tumor was taken along. Two hours after irradiation the tumors were taken out and fixed in 4% formalin. IF staining was performed on FFPE slides. RAD51 foci were detected using a non-commercial Ab provided by R. Kanaar (Erasmus MC) in a dilution of 1:5000. 53BP1 foci were detected using rabbit anti-53BP1 (A330-272A, Bethyl), diluted 1:500. As a secondary Ab for both stainings goat-anti rabbit-AlexaFluor568 (Invitrogen) was used in a dilution of 1:1000 (2 μg/mL). Images were taken by a “blinded” investigator using a confocal microscope (Leica SP5, Leica Microsystems GmbH), equipped with a 100x objective. For each tumor 5 random areas (246x246 µm) were imaged. Image stacks (~4 slices) were analyzed in ImageJ, using an in-house developed macro to automatically and objectively evaluate the RAD51 foci. Briefly, nuclei were segmented by thresholding the (median-filtered) DAPI signal, followed by a watershed operation to separate touching nuclei. For every z-stack the maximum-intensity projection of the foci signal was background-subtracted using a Difference of Gaussians method. Next, for each nucleus, foci candidates were identified as locations where the resulting pixel values exceeded the
background by a factor (typically 10-fold) times the median standard deviation of all nuclei in the image. In combination with additional filters discriminating for foci size and absolute brightness this procedure yielded a robust and reliable foci count for all nuclei. Results were validated by visual inspection.

**REV7 recruitment to local laser-induced DNA damage sites**

*pEGFP-Rev7* or *pEGFP* and *53BP1-mCherry* were co-transfected into *Brca1−/−;p53−/−* cells using X-treme GENE HP DNA Transfection Reagent according to the manufacturer's manual. GFP and mCherry double positive cells were sorted by Flow cytometry and seeded onto coverslips. Cells were sensitized by pre-incubation with Hoechst33342 and were subsequently irradiated using a 405-nm diode laser (63x objective, 0.99 mW, 60% laser power, 50 s) on a Leica SP5 confocal microscope equipped for live-cell imaging. EGFP-REV7 and 53BP1-mCherry recruitment in living cells was monitored by time-lapse imaging.

**Alpha track assay**

Cells were seeded in dishes with a mylar surface as previously described, allowing α-particle irradiation through the bottom of the dish. One or two hours post-irradiation for 3x 30 s with a 241Americium source, cells were washed once in ice-cold PBS. Subsequently, cells were extracted with cold CSK buffer (10 mM HEPES-KOH pH 7.9, 100 mM NaCl, 300 mM sucrose, 3 mM MgCl2, 1 mM EGTA, 0.5% v/v Triton-X100) and cold CSS buffer (10 mM Tris pH 7.4, 10 mM NaCl, 3 mM MgCl2, 1% v/v Tween20, 0.5% w/v sodium deoxycholate) for 5 min each before fixation in 4% PFA in PBS for 20 min at RT. Fixed cells were washed 5x in PBS+0.1% Triton-X100 and washed once in blocking solution (0.5% BSA + 0.15% glycin in PBS). Primary antibodies were diluted in blocking solution and cells were incubated overnight at 4 °C. After incubation, cells were washed 5x with PBS+0.1% Triton-X100 and washed once in blocking solution. Secondary antibodies were diluted in blocking solution and cells were incubated at RT for at least 1 h. Afterwards, cells were washed 5x in PBS+0.1% Triton-X100 and once in PBS. Finally, mylar films were glued on glass slides and cells were mounted using Vectashield with DAPI. For quantification, at least 100 53BP1 or Mre11 positive tracks were scored for the presence of RPA. Primary
antibodies used in this study were as follows: rabbit anti-53BP1 (NB100-304, Novus), 1:1000 dilution; mouse anti-RPA2 (Ab2175, Abcam), 1:500 dilution; MRE11 antibody\textsuperscript{29}, 1:200 dilution. Secondary antibodies used in this study were as follows: Alexa fluor 594 goat anti-rabbit IgG (A 31631, Invitrogen), Alexa fluor 488 goat anti-mouse IgG (A11001, Invitrogen).

**BrdU-PI cell cycle assay**

Cells were seeded in 6 cm dishes and attached overnight. Next day, cells were incubated for 15 min with 5 µM BrdU in growth medium, trypsinized, washed in PBS and fixed in 70% ethanol overnight. Fixed cells were washed in PBS, resuspended in pepsin solution (5 mg pepsin in 10 mL 0.1N HCl) and incubated for 20 min at RT. Subsequently blocking solution (0.5% Tween, 0.1% BSA in PBS) was added to wash. Next, cells were resuspended in 2 N HCl and incubated 12 min at 37 °C. To neutralize, 100 mM borate buffer (pH 8.5) was added and cells were pelleted. Anti-BrdU-FITC antibody (347583, BD Bioscience) was diluted in blocking solution, added to cells and incubated for 2 h on ice. Stained cells were washed once with blocking solution and resuspended in 500 µL PBS + 12.5 µL RNAseA + 1 µL propidium iodide (P3566, Invitrogen). Cell cycle analysis was performed the next day.

**Survival assay of mES**

\textit{R26}\textsuperscript{CreERT2/wt}, \textit{Brca1}\textsuperscript{ScD} mES\textsuperscript{15} were infected with hairpins targeting \textit{Rev7} or the vector control and selected with puromycin. Expression of mouse \textit{Brca1} were switched off by overnight incubation with 0.5 µM 4-OHT. Four days after switching, 5,000 cells of the indicated groups were seeded per well into 6-well plates and assayed for growth. Surviving colonies were fixed in formalin and stained with crystal violet.

**DR-GFP for HR assay**

\textit{R26}\textsuperscript{CreERT2/wt}, \textit{Brca1}\textsuperscript{ScD} mES were targeted with a modified version of the p59X DR-GFP construct as described\textsuperscript{30}. To allow experiments on a p53-deficient background, cells were infected with a lentiviral p53 shRNA (5’-AGAGTATTTCCACCCTCAAGAT-3’) using a pLKO1 vector provided with a
neomycin resistance marker. A G418 selected p53-deficient clone was subsequently infected with hairpins targeting Rev7 or the vector control and selected with puromycin. Expression of mouse Brca1 was switched off by overnight incubation with 0.5 μM 4-OHT to measure the effect of Rev7 loss on HR. HR reporter assays were performed by Lipofectamine 2000 (Invitrogen) transfection of l-Scel-mCherry plasmid which was generated by providing the cBasl-Scel expression plasmid with CMV-mCherry (Clontech). Forty-eight hours after transfection mCherry/GFP double-positive cells were monitored by flow cytometry as described15.

53BP1 pull-down
53BP1 pull-downs were performed as described19. Flag pull-downs were performed from 2 mg lysate prepared from MEFs following mock or NCS treatment (2 h at 250 ng/µL). Control, 53BP1, and 53BP1$^{20AQ}$ immunoprecipitates were then treated with sequential low salt (150 mM) and high salt (500 mM) RIPA buffer washes, before re-equilibration in nuclear extract buffer (20 mM HEPES pH 7.9, 100 mM KCl, 0.2 mM EDTA, 0.5 mM PMSF, 0.5 mM DTT, protease inhibitors (Roche, Complete)). Following incubation in Hela Nuclear Extract (HNE, 2 mg), control, 53BP1, and 53BP1$^{20AQ}$ complexes were washed 4x in nuclear extract buffer, then eluted with triple-Flag peptide (Sigma).

Immunoglobulin class switch recombination
CH12 cells were either mock treated or stimulated with agonist anti-CD40 antibody (0.5 μg/mL; eBioscience; HM40-3), mouse IL-4 (5 ng/µL; R&D Systems) and TGF-β1 (1.25 ng/µL; R&D Systems). Cell-surface IgA expression was determined by flow cytometry, immunostaining with biotinylated anti-mouse IgA antibody (eBioscience; 13-5994), and Alexa488-streptavidin conjugate (Life Technologies).

CFSE assay
Cell proliferation was assessed in stimulated CH12 cells using CFSE according to manufacturer’s instructions (CellTrace™; Life Technologies).
Chromatin Immunoprecipitation

Each ChIP was performed from chromatin prepared from ~10^7 CH12 cells stimulated for 30 h with agonist CD40 antibody, IL-4, and TGF-β essentially as described\(^19\). For each individual ChIP, 4 µg of RPA34- 20 (Ab-3, Calbiochem), 2 µg H2a.X (3522-1, Epitomics), or 4 µg control mouse anti-IgG (sc-2025; Santa Cruz) coupled to 25 µL Protein-G Dynabeads® (Life Technologies, 10003D) was used. Quantities of immunoprecipitated chromatin were calculated relative to total input chromatin by quantitative PCR in duplicate on an CFX96 Real-Time Analyzer (Biorad) with the use of iQ SYBR® Green (Biorad) for each primer pair (see table below).

Immunohistochemistry on paraffin sections
The panel of formalin-fixed, paraffin-embedded archival specimens from a series of 50 human primary breast carcinomas was examined, surgically resected before any chemotherapy or radiotherapy. In parallel, sections from 10 specimens of formalin-fixed, paraffin-embedded histologically normal human breast tissues were used as normal tissue controls, for immunohistochemical analysis of REV7 expression patterns. The breast carcinomas were all of the triple-negative type, defined in this cohort as having fewer than 1% tumor cells positive in standard immunohistochemical staining for estrogen receptor and progesterone receptor proteins, and lacking amplification of the HER2 (also known as ERBB2) gene. For the immunohistochemical analysis, 4-μm thick sections were cut from representative blocks of the tumour tissues, the sections were deparaffinized and processed for sensitive immunoperoxidase staining with the primary mouse monoclonal antibody to REV7 (BD Biosciences, #612266, diluted 1:100). The staining procedure was essentially as described\textsuperscript{15}, with antigen unmasking in citrate buffer, pH 6.0 for 15-20 min in microwave oven, and overnight incubation with the primary antibody, followed by the Vectastain Elite kit (Vector Laboratories) and nickel sulphate enhancement without nuclear counterstaining\textsuperscript{31}. Mouse normal serum and antibody to γH2AX served as negative and positive controls, respectively. Evaluation of the staining patterns was performed by two independent observers (with very similar outcome) including a senior oncopathologist with over 20 years of experience with breast cancer pathology. The results were scored in the following categories, based on comparison of cancer cells with the series of normal breast tissue controls, and also the normal cells present within each of the tumour sections. As normal breast epithelium showed reproducible positivity for REV7 protein in over 90% of cells, we considered as aberrantly decreased expression in a tumour when fewer than 70% of cancer cells were positive. In addition to percentage of stained tumour cells, staining intensity was classified as either normal (comparable with the intensity of normal cells present on each section) or aberrantly low (clearly below the intensity seen in adjacent normal cells, and up to undetectable in some cases). Overall, while 6 of 47 informative cases showed concomitantly aberrant fraction of REV7-stained cells and reduced intensity of staining, 12 additional cases showed less pronounced defects.
limited to either staining intensity or reduced percentage of cancer cells, respectively. As the primary goal of these analyses was to establish a detection assay for REV7 on archival tissue specimens and to assess the frequency of potentially REV7-deficient breast tumours, correlation analyses with clinical parameters including treatment outcome remain to be performed on larger cohorts of patients in the future.

**Statistics**

Statistical test used were log-rank test, t-test and Mann–Whitney U test, with $P < 0.05$ as the significance level. No statistical methods were used to predetermine sample size.
Extended Data Figure 1 | Loss of Rev7 causes PARPi resistance in vitro and in vivo. a, Quantification of Rev7 transcript levels in KB1P-B11 cells
transduced with Rev7-targeting shRNAs or the vector control. Hprt was used as a control for transcript expression. The data represent the mean ± s.d. b-c, Cell proliferation rates in KB1P-G3 (b) or –B11 (c) cells analyzed using the MTT assay. d-g, Long-term clonogenic survival assays and quantification of KB1P-G3 (d, f) or –B11 (e, g) cells transduced with the indicated constructs and treatments. All the groups were normalized by the absorbance of the vector control. The data represent the mean ± s.d. h, Quantification of the real colony numbers from the short term clonogenic survival assay of KB1P-G3 cells with or without Rev7 loss exposed to olaparib. i, REV7 protein levels were determined by western blotting of lysates derived from KB1P-G3 cells transduced with the indicated constructs. j, Overall survival of mice with KB1P-B11-derived Rev7-depleted or control tumors treated with one regimen of 50 mg/kg olaparib daily for 28 d or left untreated. The P value was calculated using the log-rank test. k, l, relative tumor growth of individual KB1P-G3 (k) and KB1P-B11 (l)-derived Rev7-depleted or control tumors treated with one regimen of 50 mg/kg olaparib daily for 28 d or left untreated.

Extended Data Figure 2 | Loss of REV7 causes olaparib resistance in BRCA1-deficient SUM149PT cells. a, Western blotting analysis of REV7 or 53BP1 expression in SUM149PT cells transduced with REV7- or 53BP1-targeting hairpins or the vector control. b, Example of a long-term clonogenic survival assay using the indicated hairpins and olaparib concentrations. c, Quantification of the clonogenic assays using absorbance of crystal violet at 590 nm. The data represent the mean ± s.d. All the groups were normalized by the absorbance of the vector control and showed significant differences to the control (P< 0.01, t-test).
Extended Data Figure 3 | Rev1 or Rev3 inhibition and PARPi sensitivity of Brca1<sup>−/−</sup>; p53<sup>−/−</sup> mammary tumor cells. a-b, Quantification of Rev1 (a) or Rev3 (b) transcript levels in KB1P-G3 cells transduced with Rev1-or Rev3-targeting shRNAs or the vector control. Hprt was used as a control for transcript expression. The data represent the mean ± s.d. c, Long-term clonogenic survival assays of KB1P-G3 cells exposed to the indicated PARP inhibitors. d, Quantification of the clonogenic assay by determining the absorbance of crystal violet at 590 nm. All the groups were normalized by the absorbance of the vector control. The data represent the mean ± s.d. e-f, Quantification of Rev7 transcript (e) or protein (f) levels in KB1P-G3 cells transduced with Rev7-targeting shRNAs or the vector control. Hprt was used as a control for transcript expression. The data represent the mean ± s.d. g, GFP-tagged REV7 mutants recruitment to sites of DNA damage was observed 5 min after 405 nm laser exposure (0.99 mW, 60% laser power, 50 s) in KB1P-B11 cells. Scale bar, 10 μm.

Extended Data Figure 4 | REV7 recruitment to the DNA damage sites in human cells. | a-d, Human REV7 recruitment to sites of laser-induced DNA damage were analyzed in siRNF8, siRNF168 (a) si53BP1 (c) and siGFP U2OS cells. RNF8 and RNF168 protein levels were determined by western blotting (b) using lysates derived from U2OS cells transfecting with the indicated siRNAs. For the quantification of the REV7 signal within laser-induced DNA damage stripes (d), a minimum of 100 striped (i.e. γH2AX-positive) cells were analyzed for the presence of the REV7 signal in 2 independent experiments. White scale bars = 50 μm. e, RAD51 focus (red) formation in KB1P-B11 cells before and 5 h post-IR (10 Gy). Scale bar, 10 μm. f, Quantification of RAD51 foci in KB1P-B11 cells in the presence or absence of REV7 depletion. At least 150 cells were analyzed per group in 3 independent experiments each. Error bars indicate s.d; IR= 5 h post-IR (10 Gy). g, Western blotting analysis of REV7-depleted KB1P-G3 cells transfected with human REV7-GFP or shRev7-resistant mouse Rev7-GFP fusion proteins. h, Same assay as in (e, f) using the ATM inhibitor KU55933 with or without IR (5 h post-IR (10 Gy)). i, Long-term clonogenic
survival assay of KB1P-G3 cells exposed to olaparib in the presence or absence of KU55933 pre-treatment.

Extended Data Figure 4
Extended Data Figure 5 | Loss of Rev7 does not cause PARPi resistance in Brca2\(^{-/-}\); p53\(^{-/-}\) or p53\(^{-/-}\) mammary tumor cells in vitro. a, b, Quantification of Rev7 transcript levels in Brca2\(^{-/-}\);p53\(^{-/-}\) (KB2P_1.21 or KB2P_3.4) cells transduced with Rev7-targeting shRNAs or the vector control. Hprt was used as a control for transcript expression. The data represent the mean ± s.d. c-f, Long-term clonogenic survival assays and quantification of KB2P_1.21 or KB2P_3.4 cells with or without Rev7 depletion exposed to the indicated treatments. All the groups were normalized by the absorbance of the vector control. The data represent the mean ± s.d. g, Quantification of Rev7 transcript levels in p53\(^{-/-}\) (KP3.33) cells transduced with the indicated constructs. Hprt was used as a control for transcript expression and the data represent the mean ± s.d. h, i, Long-term clonogenic survival assays and quantification of KP3.33 cells exposed to the indicated treatments. The data represent the mean ± s.d.

Extended Data Figure 6 | Rev7 loss promotes end resection at DSBs in BRCA1-deficient cells after IR. a, Quantification of RPA-positive alpha tracks in KB1P-B11 cells 1 or 2 h after irradiation with alpha particles. b, Quantification of RPA and 53BP1-positive alpha tracks in KB1P-B11 cells transfected with non-targeting control siRNAs or siRNAs against CtIP. c, Cell cycle analysis (BrdU incorporation and propidium iodine labeling) of KB1P-B11 cells transduced with the indicated constructs and siRNAs. d, e, Quantification of Rev7 transcript (d) or protein (e) levels in BRCA1-deficient mES cells transduced with Rev7-targeting shRNAs or the vector control. Hprt was used as a control for transcript expression. The data represent the mean ± s.d. f, Representative images of surviving colonies of Brca1\(^{-/-}\) mES cells that were transduced with an empty vector control or Rev7-targeting shRNAs. g, Quantification of colony formation normalized to the vector control. h, Quantification of RAD51 foci in Brca1\(^{-/-}\) mES cells that were transduced with the indicated constructs.
Extended Data Figure 7 | REV7 loss frequently occurs in triple-negative breast cancer.  

**a, b,** Quantification of hREV7 transcript levels (a) and protein levels (b) in U2OS cells transduced with indicated constructs. Two different pairs of primers for hREV7 or hHPRT were used for the quantification of hREV7 transcript levels.  

**c-e,** Examples of aberrantly reduced REV7 protein expression in triple-negative human breast carcinomas. Immunohistochemical detection of REV7 in human breast carcinomas shows moderate to high nuclear expression in normal human breast tissue (data not shown) and the majority of invasive...
breast tumors (c). Aberrant reduction of REV7 with less than 70% of cancer cells that show nuclear positivity (d, e) was observed in 18/50 cases.

Extended Data Figure 8

**Extended Data Figure 8 | REV7 is a downstream effector of 53BP1.**

**a,** Quantification of 53BP1 foci in KB1P-G3 cells in the presence or absence of REV7 depletion. At least 100 cells were analyzed per group in 3 independent experiments each. Error bars indicate ±s.d.; IR = 5 h post-IR (10 Gy). **b,** REV7 or 53BP1 protein levels were determined by western blotting of lysates derived
from MEF cells transduced with the indicated constructs. c, d, RIF1 foci formation (c) following neocarzinostatin treatment and quantification of RIF1 foci (d) in MEF cells in the presence or absence of REV7 or 53BP1 depletion. e, Flag-pulldowns were performed from 2 mg lysate prepared from 53BP1−/−, 53BP1−/−+53BP1 and 53BP1−/−+53BP120AQ MEFs following mock or NCS treatment. Control, 53BP1, and 53BP120AQ immunoprecipitates were incubated in Hela Nuclear Extract (HNE, 2 mg) and then eluted with triple-Flag peptide.

Extended Data Figure 9 | The effect of REV7 inhibition on CSR after antigenic stimulation of CH12 cells. a, Rev7 mRNA levels determined by qRT-PCR were normalized against β-actin transcripts in the indicated shRNA-transduced CH12 cell-lines. The data represent the mean ± SEM from two primer sets specific for Rev7 transcript. b, 53BP1 protein of each group normalized to vector-transduced cells (CH12) was analyzed by western blotting. c, IgH μ and α germline transcripts and AID (Aicda) mRNA were estimated by semi-quantitative RT-PCR using 2-fold serial dilutions of cDNA made from indicated CH12 cell-lines 40 h following stimulation. Hprt was used as a control for transcript expression. d, Representative flow cytometric profiles of shRNA-transduced CH12 B cells stained with anti-IgA antibody 40 h following stimulation with indicated cytokines. e, Cells (CH12) were labeled with CFSE immediately before cytokine stimulation as in Fig. 4d, and cell proliferation was assessed by flow cytometry at indicated time points. f, Quantification of CSR to IgA of shRNA-transduced CH12 cells 40 h post-stimulation with CD40Ab, IL-4, TGFβ-1 (CIT). Data represent the mean ± s.d. from 2 independent experiments performed in triplicate.

Figure A1

Figure A1 | REV7 loss does not cause PARPi resistance of 53BP1 loss

Brca1<sup>−/−</sup>;p53<sup>−/−</sup> tumor cells. a, REV7 or 53BP1 or both were targeted in mouse Brca1<sup>−/−</sup>;p53<sup>−/−</sup> cells (G3) using the indicated hairpins resulting in efficient protein loss. b, Quantification of MRE11-labelled RPA-positive alpha tracks of KP3.33 or KB1P-G3 cells transduced with the indicated constructs 2h post IR. c, d, Long-term clonogenic assay (c) and quantification (d) of KB1P-G3-sh53bp1 cells transduced with the indicated constructs. All the groups were normalized by the absorbance of the sh53bp1-GFP control. The data represent the mean ± s.d.
Figure A2 | Recruitment of REV7 to DNA damage sites is sensitive to proteasome inhibition. Human U2OS cells were treated with the indicated proteasome inhibitors (5μM) or DMSO (vehicle control) for 2.5h, exposed to laser micro-irradiation and then stained with antibodies against REV7 and γH2AX, respectively – as indicated.

Figure A3
Figure A3 | Rev7 was among the top outliers of genes that were downregulated in resistant tumors by Detection of Imbalanced Differential Signal (DIDS) algorithm analysis. DIDS analysis on the RNAseq data from 55 PARPi resistant spontaneous tumors and their matched controls was performed. More than 50% inhibition of the Rev7 transcript levels in 6 out of 55 PARPi resistant tumors was found, which was confirmed by Western blotting to quantitate REV7 protein levels (data not shown). OT = orthotopic transplantation. P value and DIDS score were determined as previously described32.

Figure A4

Figure A4 | Effect of REV7 depletion on cisplatin sensitivity in PARPi-resistant tumors. Survival of mice that carry either REV7-depleted PARPi resistant tumors (blue) or the matched PARPi-sensitive controls with normal REV7 levels (red). Animals were treated with saline solution or cisplatin as indicated. When tumors reached an approximate size of 200mm³, mice were either treated with saline solution or a dose of 6mg of cisplatin per kg i.v., which is the maximum tolerated dose in this strain. The REV7 depleted PARPi resistant tumors were still hypersensitive and shrank in response to cisplatin but
they relapsed significantly faster (P<0.003, log rank test) when compared with the corresponding drug-sensitive tumors that were treated with cisplatin.

Figure A5

Figure A5 | Distribution of REV7 staining reveals that loss of REV7 expression is more frequent in triple negative breast cancer (TNBC).

a, A cohort of breast cancer specimens from the NKI biobank, available in the form of tissue microarrays of breast cancers (random subtypes), was subjected to immunohistochemistry to evaluate REV7 and 53BP1 protein expression. P=0.009 (the Wilcoxon rank sum test with continuity correction). TRUE: TNBC, FALSE: the rest. b, Distribution of REV7 and 53BP1 staining in breast cancer patients reveals the trend for mutually exclusive defects in 53BP1 and REV7 expression.
